

## Atlantic Mackerel Update for 2017 Specifications

28 April 2016  
Population Dynamics Branch  
National Marine Fisheries Service, Northeast Fisheries Science Center  
Woods Hole, MA 02543

The following information addresses the request by Dr. Chris Moore, Executive Director of the Mid-Atlantic Fisheries Management Council (MAFMC), in his letter to Dr. Bill Karp on 20 January 2016. The MAFMC requested that the NEFSC provide a data update for Atlantic mackerel for this year's specifications.

### *Catch*

Mackerel total catch averaged 112,000 metric tons (mt) from 1960 through the end of foreign catches in 1991 (Table 1, Figure 1). From 1992 through 2001, catches averaged only 33,100 mt before increasing to a peak of 111,900 mt in 2006. Total catch then declined and since 2011 has averaged 12,400 mt. U.S. discards, the only discard estimates available, represented an average of 2.7% of U.S. landings over the time series, and 1.4% of landings since 2000. Since the implementation of annual catch limits in 2011, total catch has been less than 40% of the annual ABC's, with the exception of 2015 where catch was approximately 51% of the ABC (Table 2). Updated age and length catch composition data were not available.

The spatial distribution of total commercial landings from dealer reports for 2005-2009 and 2010-2014, as well as vessel trip report (VTR) estimates from 2015 are depicted in the appendix.

### *NEFSC spring survey indices*

Aggregate relative abundance (arithmetic stratified mean number-per-tow) and biomass (arithmetic stratified mean kg-per-tow) indices were derived using data from the NEFSC spring bottom trawl survey conducted during 1968-2015. Indices were not yet available for the ongoing 2016 spring survey. In 2009, the survey changed primary research vessels from the *Albatross IV* to the *Henry B. Bigelow*. Indices for 2009 onward were converted from *Bigelow* units to *Albatross IV* equivalents using single conversion factors for relative abundance (1.188) and biomass (0.868) (Miller et al. 2010). In 2014, stations south of Maryland (offshore strata 61-68) were not sampled due to delays in the survey (Figure 2). Accordingly, 1968-2013 indices were previously re-estimated using an abbreviated set of offshore strata and compared to estimates based on the full offshore strata set historically used to estimate mackerel spring survey indices (NEFSC 2015). This comparison indicated that the use of an abbreviated set of strata did not impact temporal trends in relative abundance or biomass; therefore, the abbreviated set of offshore strata was used to derive relative abundance and biomass indices from 1968-2015 so that the 2015 estimate could be directly compared to that of 2014. Estimated 2015 indices of relative abundance and biomass were 97.64 mackerel-per-tow (CV = 46.5%) and 10.56 kg-per-

tow ( $CV = 60.5\%$ ), respectively (Table 3). Estimated 2015 relative abundance and biomass indices were both higher than the time series medians of 22.13 mackerel-per-tow and 4.13 kg-per-tow (Figure 3).

Mackerel lengths from the spring survey ranged from 11 cm to 48 cm during 1968-2015. Length compositions varied over time, with some years exhibiting unimodal distributions and other years exhibiting bimodal or trimodal distributions (Table 4, Figure 4). Annual stratified mean proportions-at-length were averaged over ten-year intervals, with the exception of the earliest two time periods which included nine years, to further examine changes in length composition over time. Mackerel length structure expanded between the first (1968-1976) and second (1977-1985) time intervals, but contracted thereafter (Figure 5). During the most recent time interval (2006-2015), mackerel size composition range was the smallest of the time series, with 96% of individuals between 18 cm and 31cm fork length. Average length structure was trimodal during the first 29 years of the time series, but then became bimodal (modes = 20 cm and 27 cm) from 1995 onward (Figure 5). Average annual length over the time series was also analyzed (Figure 6). Average length exhibited substantial interannual variability, but generally increased over beginning of the time series, reaching a peak in 1981, and then declined over the latter part of the time series.

While not requested in the MAFMC's letter, age-specific indices of mackerel from the NEFSC spring bottom trawl survey were updated. Age-specific indices as geometric stratified mean number-per-tow-at-age were updated from the 2010 TRAC through 2013 using the full offshore strata set (Table 5, Figure 7). Indices from years 2009 through 2013 were converted from *Bigelow* units to *Albatross IV* equivalents. Age-specific indices suggested a truncation in age structure since approximately 2001. Geometric mean indices could not be updated for the entire time series using the abbreviated strata set, so stratified arithmetic mean indices-at-age were developed for the *Bigelow* years (2009-2015) using the abbreviated strata set (Table 6, Figure 8). Since all years were from the *R/V Bigelow*, relative abundance estimates were not converted to *Albatross IV* equivalents. Indices-at-age were predominantly comprised of one through three year-old fish.

### *Canadian mackerel assessment*

In 2012, the Canadian Department of Fisheries and Oceans (DFO) assessed the Canadian contingent of Atlantic mackerel in NAFO Subareas 3 and 4 (DFO 2012). A sequential population analysis was conducted using time series of Canadian landings-at-age (1968-2011) and spawning stock biomass indices from the southern Gulf of St. Lawrence egg survey (1996-2011). Catches from bait and recreational fisheries were not recorded, and commercial discards did not appear to be available for the analysis. Canadian landings increased in the early 2000's, reaching a historic high in 2005. Landings were variable but generally decreased beginning in 2006, reaching a low in 2011. Spawning stock indices from egg surveys exhibited a decline between 1993-1998, subsequently increased due to a strong-1999 year class, and then declined to historical lows since 2005. A 2009 egg survey on the Scotian Shelf and southern Newfoundland coast also exhibited low egg densities.

The assessment indicated a decline in estimated mackerel spawning stock biomass since approximately 2006 (Figure 9). This decline was attributed to low recruitment and high fishing mortality rates (Figure 10). The assessment noted a slight retrospective pattern for predicted abundance and fishing mortality but not for spawning stock biomass, and further noted that the diagnostics did not suggest any major adjustment problems (Grégoire et al. 2014).

Total spawning stock biomass in 2011 ( $SSB_{2011}$ ) was estimated to be 72,175 tons and fishing mortality ( $F_{2011}$ ) was estimated to be 0.137 (Grégoire et al. 2014). The ratio between  $F_{2011}$  and  $F_{40\%}$  was 0.7, and the ratio between  $SSB_{2011}$  and  $SSB_{MSY}$  was 0.515 and 0.543 for the analytical and random methods, respectively. Accordingly, the mackerel stock was described as overfished but without overfishing in 2011. The assessment recommended a reduction in fishing mortality compared to the 2011 estimate and that catches in 2012-2013 should not exceed 9,000 mt.

An Icelandic project is currently underway to investigate Atlantic mackerel stock structure in the North Atlantic and both the U.S. and Canada have contributed samples for this project. A University of Maryland project is also underway to investigate mackerel contingent structure in the northwest Atlantic through the use of otolith stable isotopes. However, at this time no additional information is available regarding Atlantic mackerel stock structure in the northwest Atlantic and in particular whether the U.S. and Canadian contingents should be classified as two distinct mackerel stocks or one unit stock. The NEFSC received funding to identify and stage mackerel eggs from shelf-wide ichthyoplankton surveys to estimate total annual egg production of the southern spawning contingent. These total annual egg production estimates will then be combined with those of the northern contingent (estimated through DFO's egg survey) and evaluated as an index of spawning stock biomass.

Figure 1: Total annual mackerel catch by the U.S., Canada and other countries for 1960-2015.

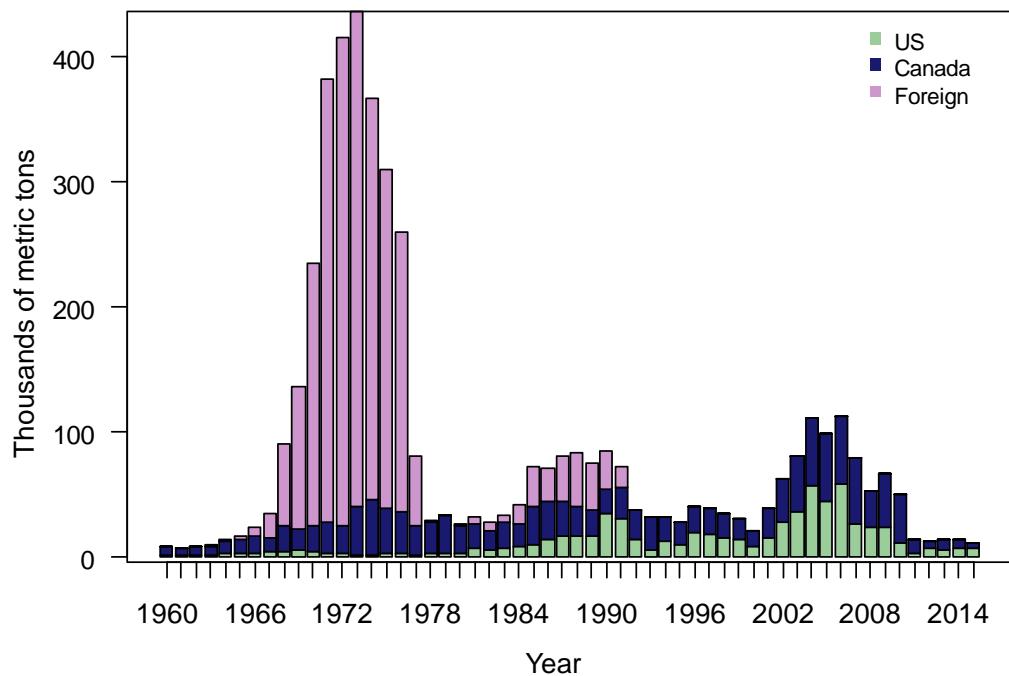

Figure 2: Offshore depth strata from the NEFSC bottom trawl research surveys. Some of these strata may not be sampled presently.

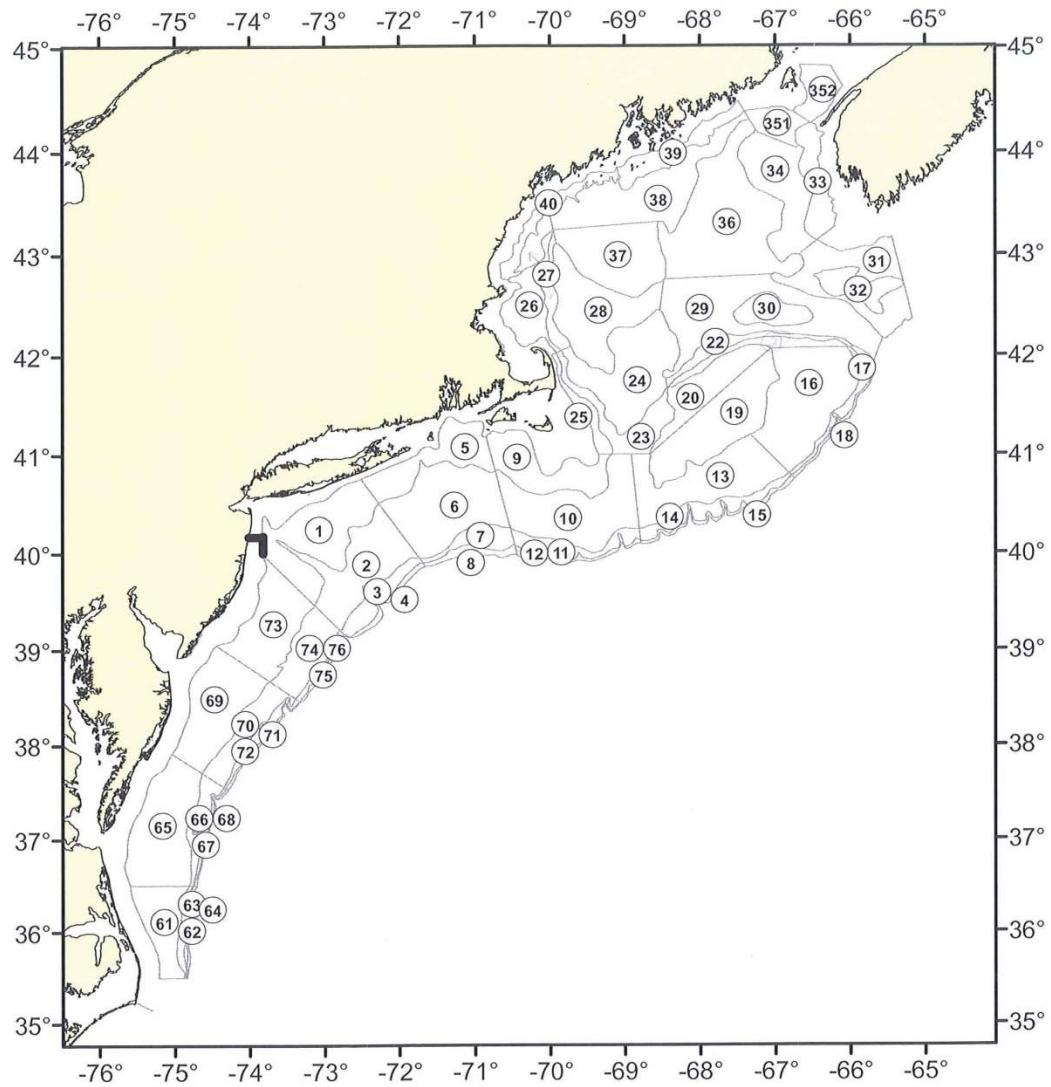

Figure 3: Atlantic mackerel relative abundance (stratified mean number-per-tow) and biomass (stratified mean kg-per-tow) indices derived from the NEFSC spring bottom trawl survey for 1968-2015. The median number- and weight-per-tow values represent the median indices over 1968-2015.

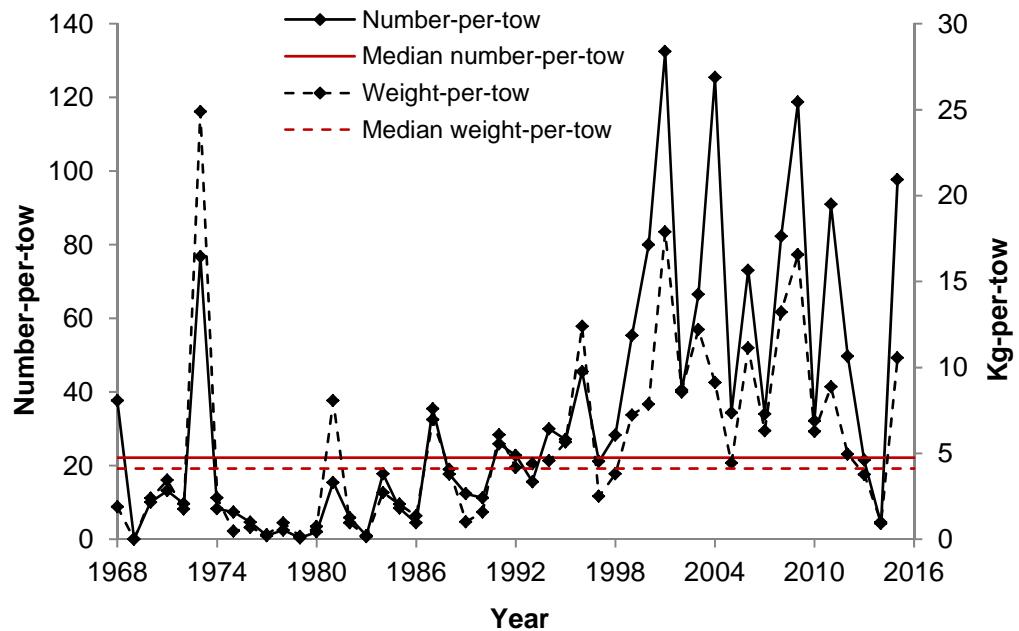

Figure 4: Annual mackerel length compositions from the NEFSC spring bottom trawl survey, 1968-2015.

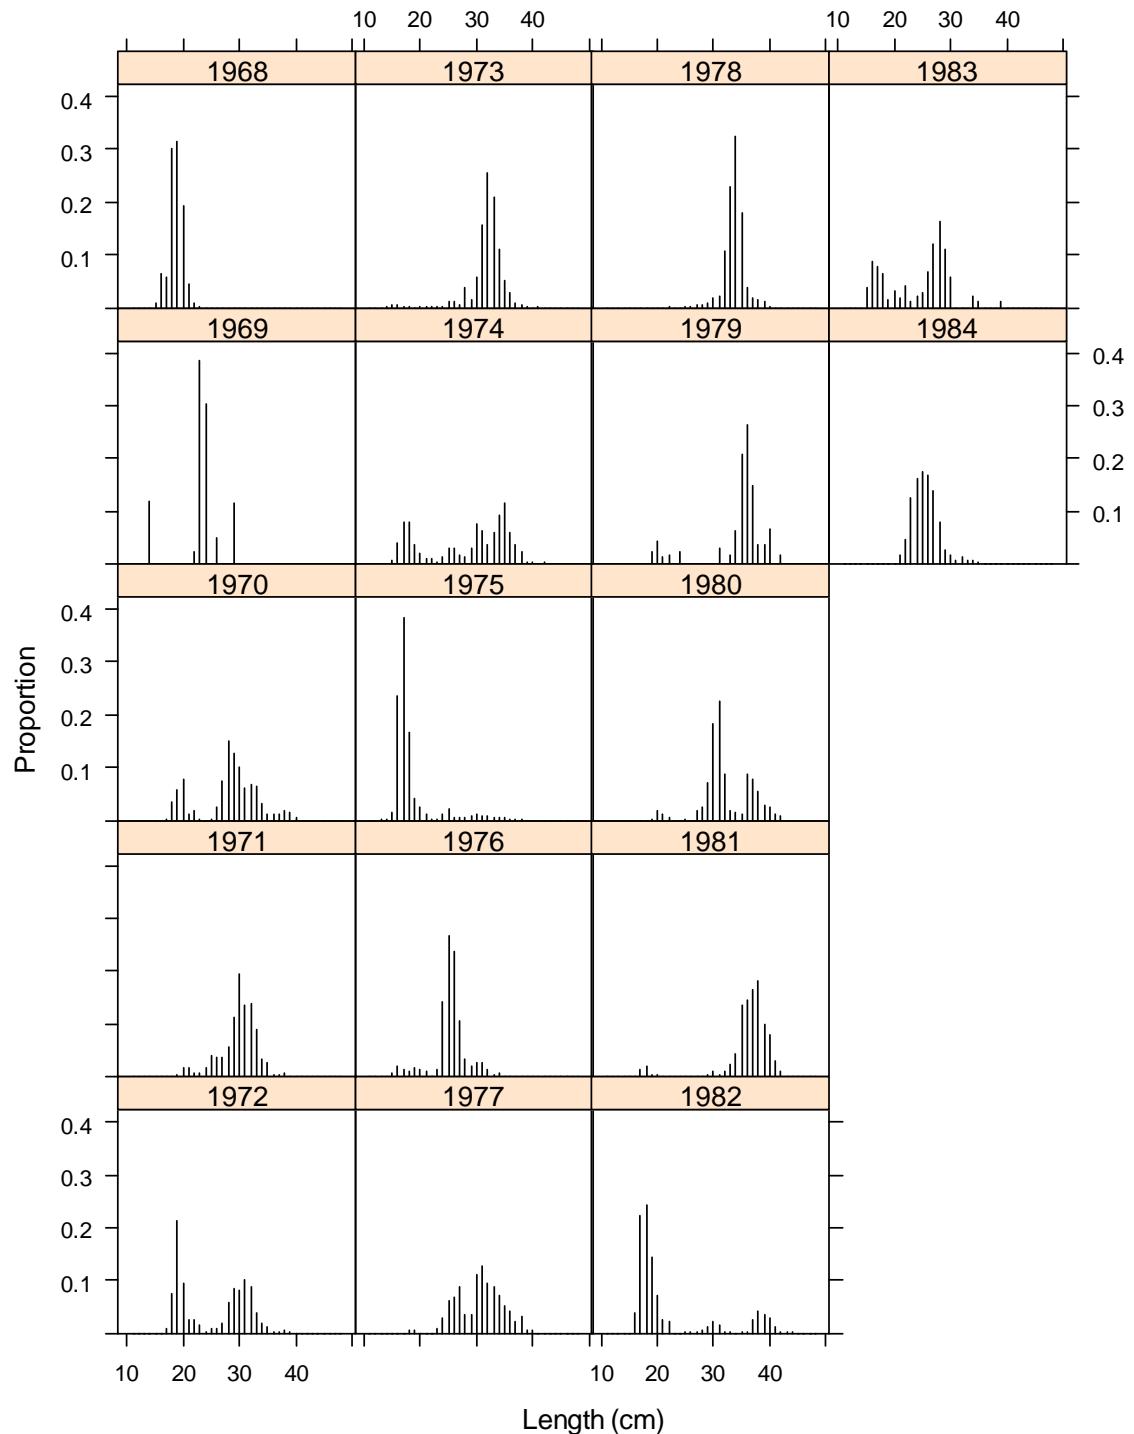

Figure 4, continued

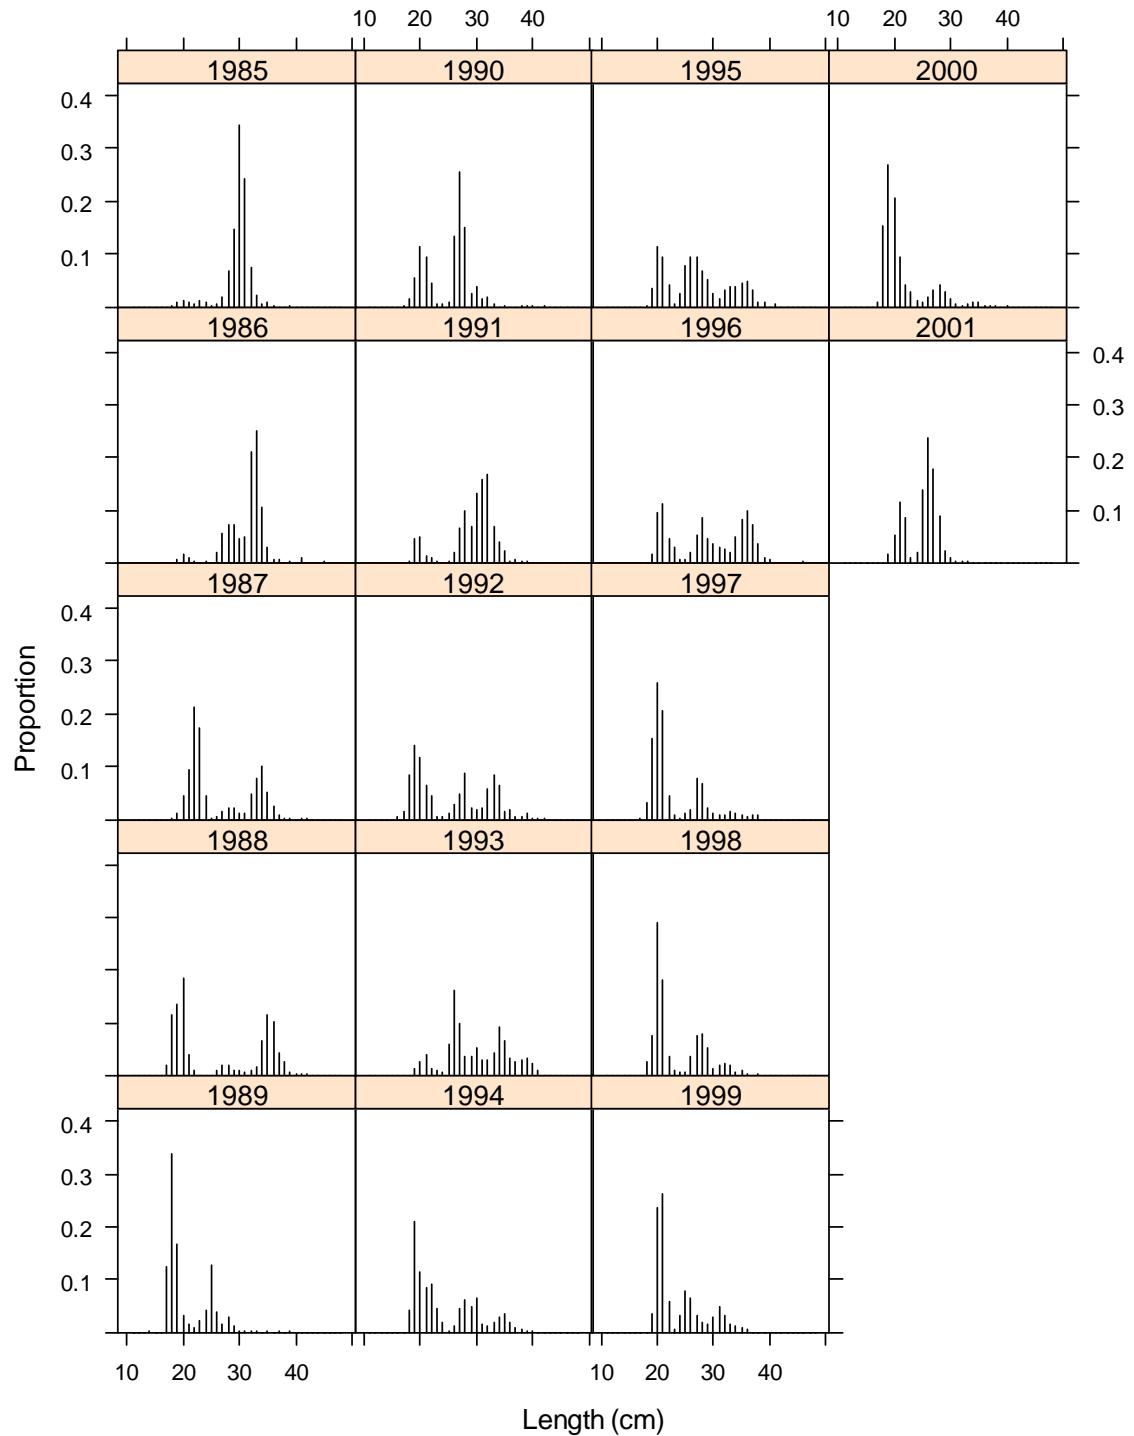

Figure 4, continued

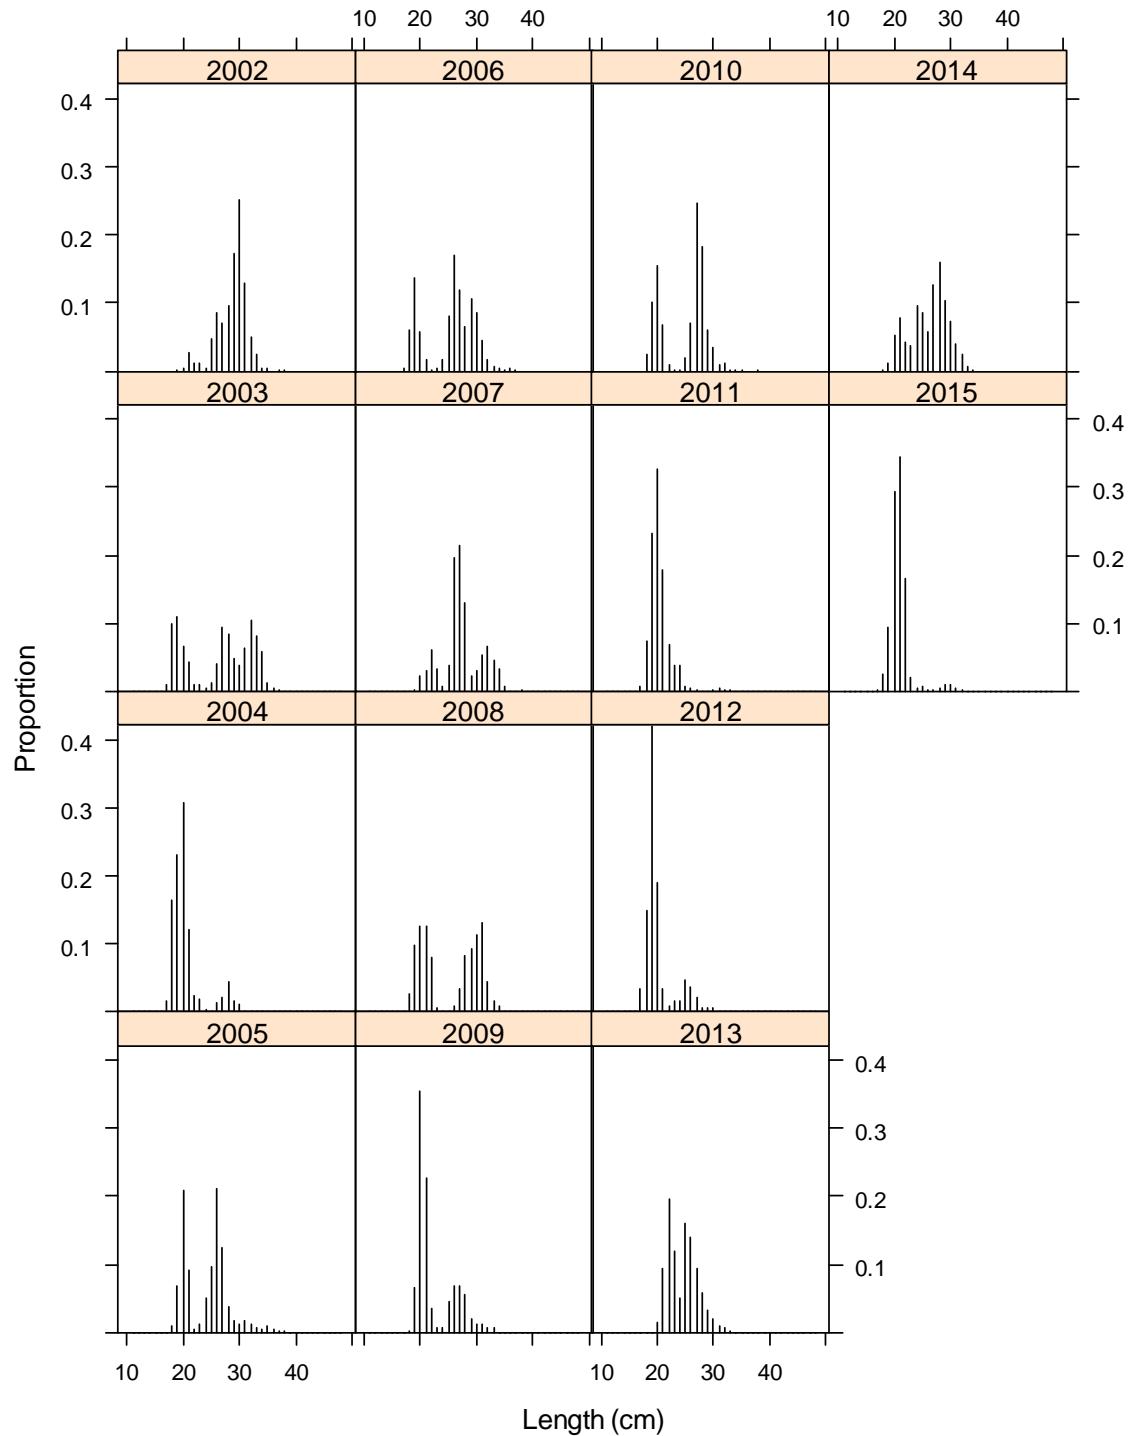

Figure 5: Annual mackerel length compositions (stratified mean numbers-at-length), averaged over nine or ten year time intervals, from the NEFSC spring bottom trawl survey for 1968-2015.

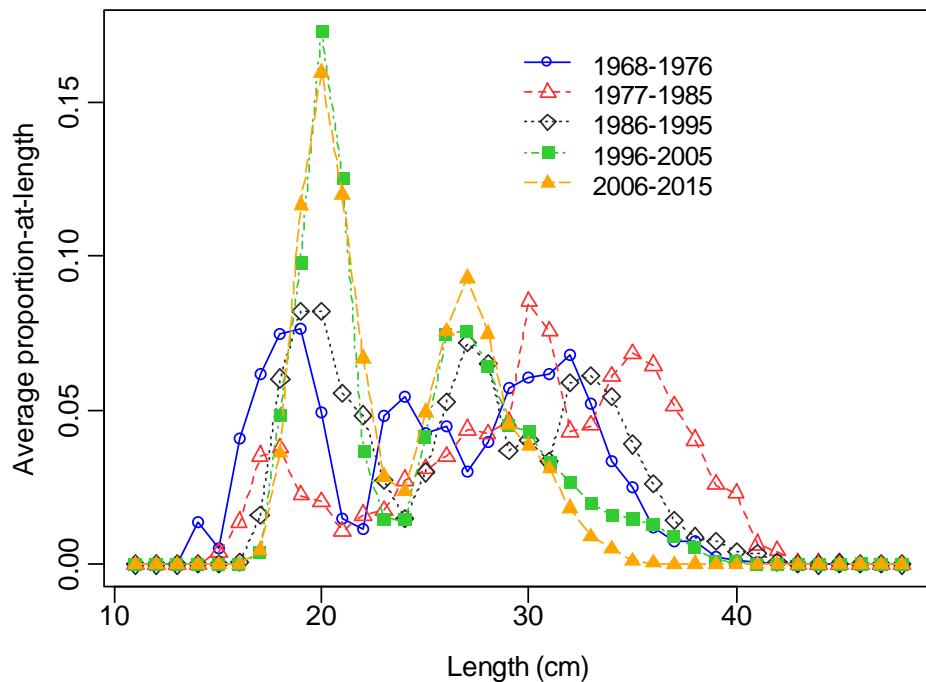

Figure 6: Stratified mean length of mackerel from the NEFSC spring bottom trawl survey, 1968-2015.

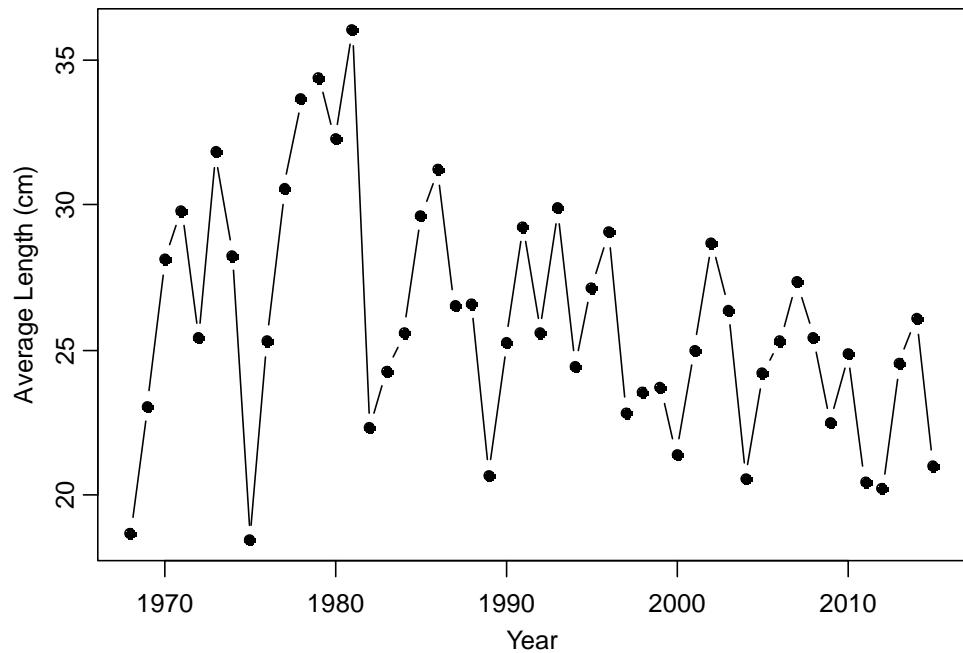

Figure 7: Proportions-at-age of Atlantic mackerel in the NEFSC spring survey from 1968-2013, calculated from geometric mean age-specific indices.

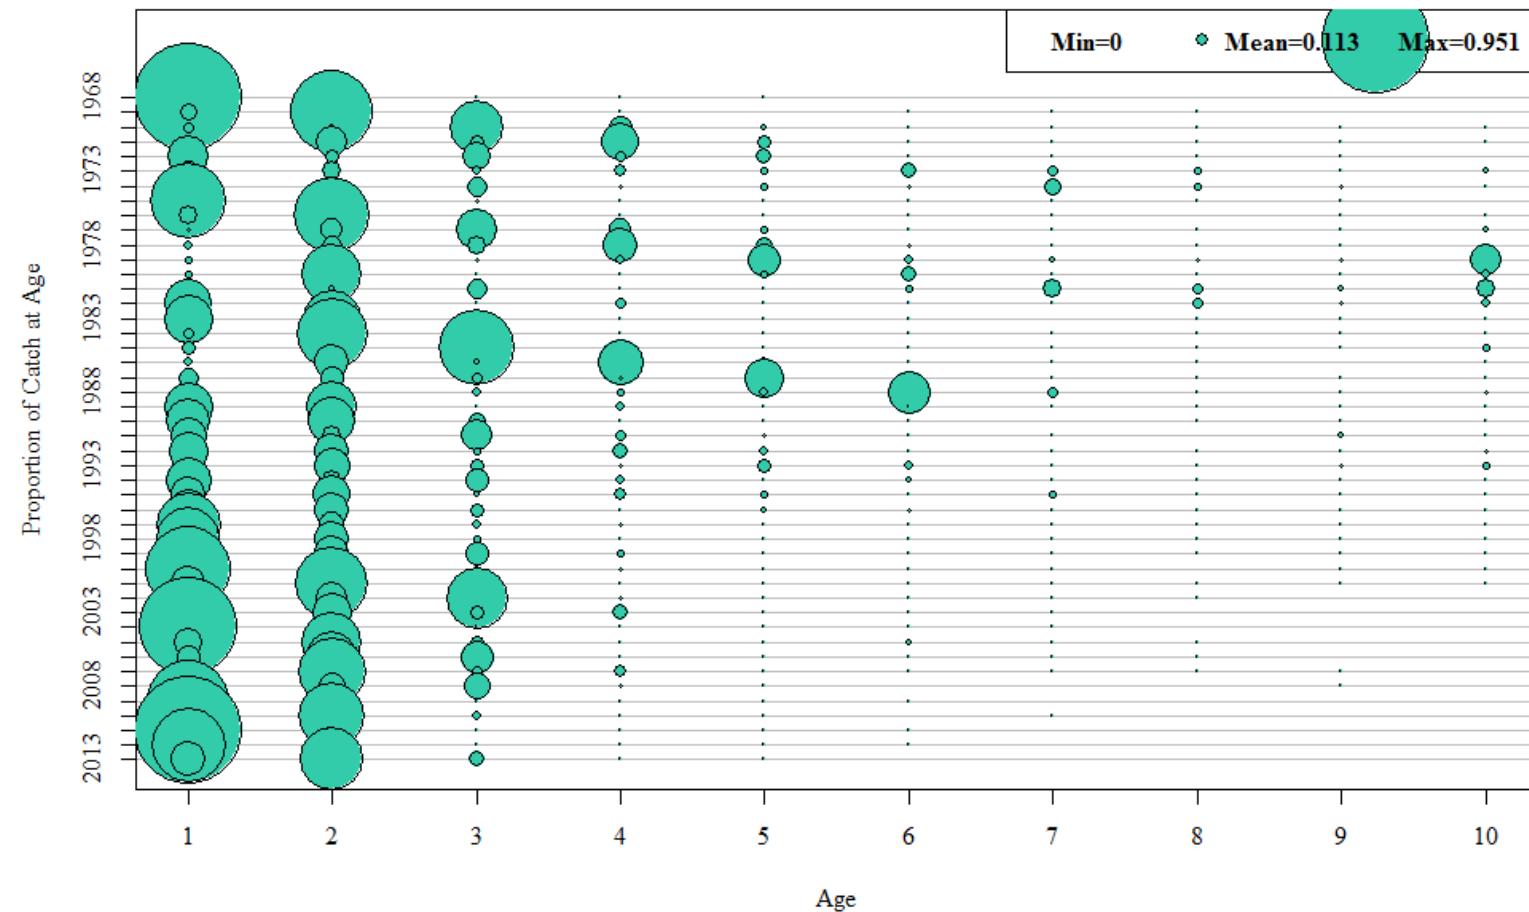

Figure 8: Proportions-at-age of Atlantic mackerel in the NEFSC spring survey from 2009-2015, calculated from arithmetic mean age-specific indices.

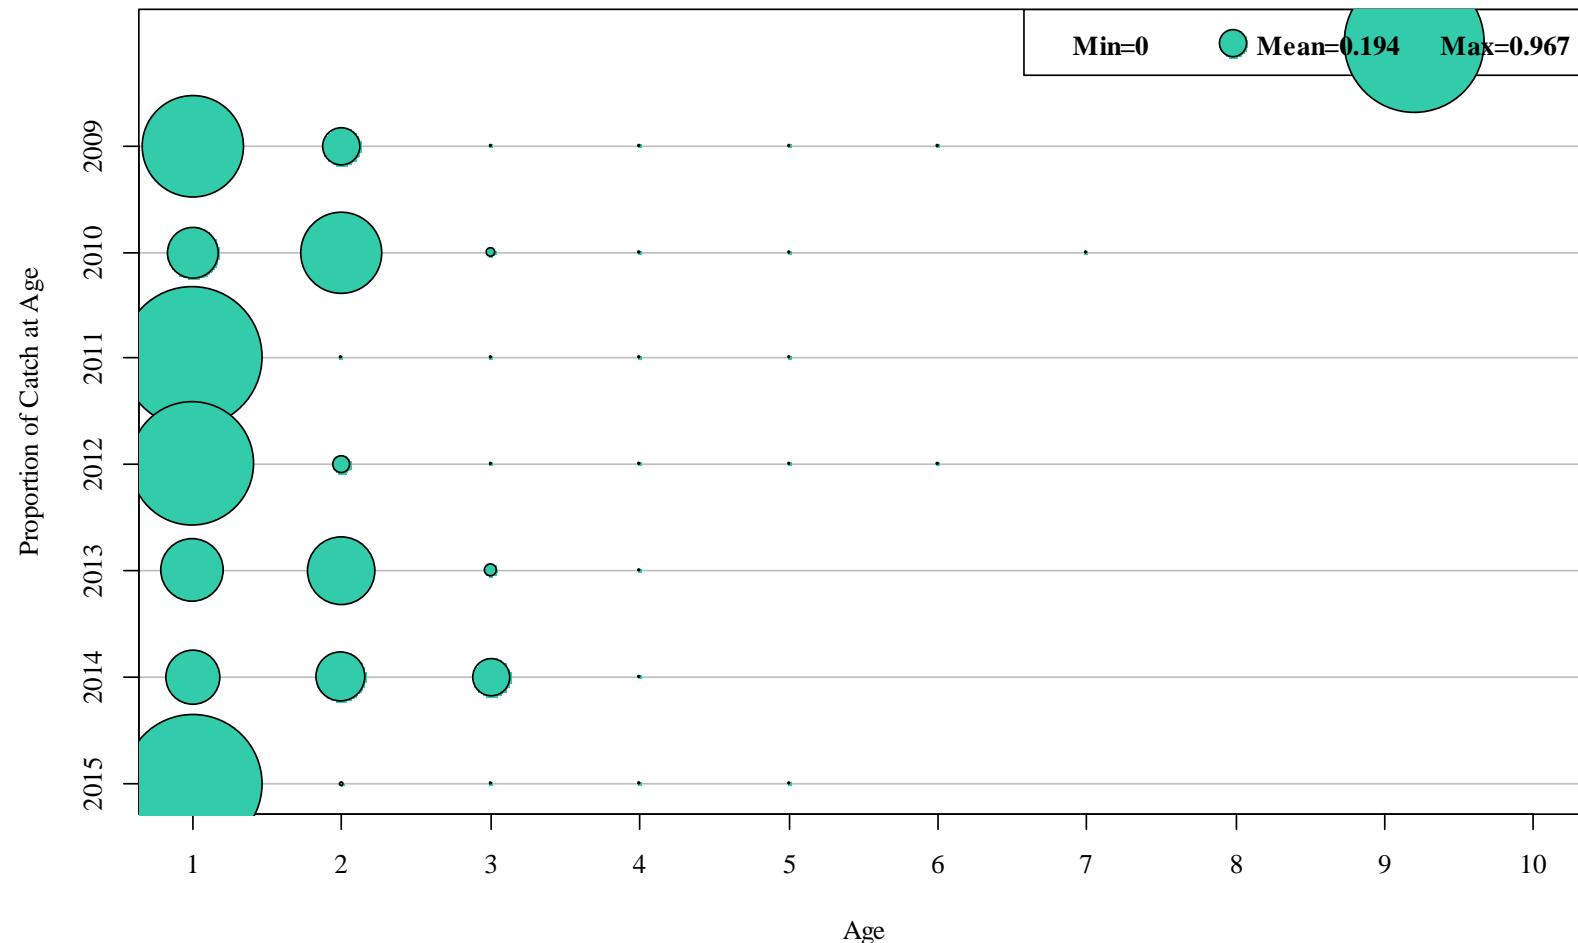

Figure 9: Atlantic mackerel total and spawning stock biomass (tons) in NAFO Subareas 3 and 4 from 1968 to 2011, estimated from a sequential population analysis of the Canadian contingent of mackerel (Reprinted from the 2012 Canadian assessment (DFO 2012, Figure 14)).

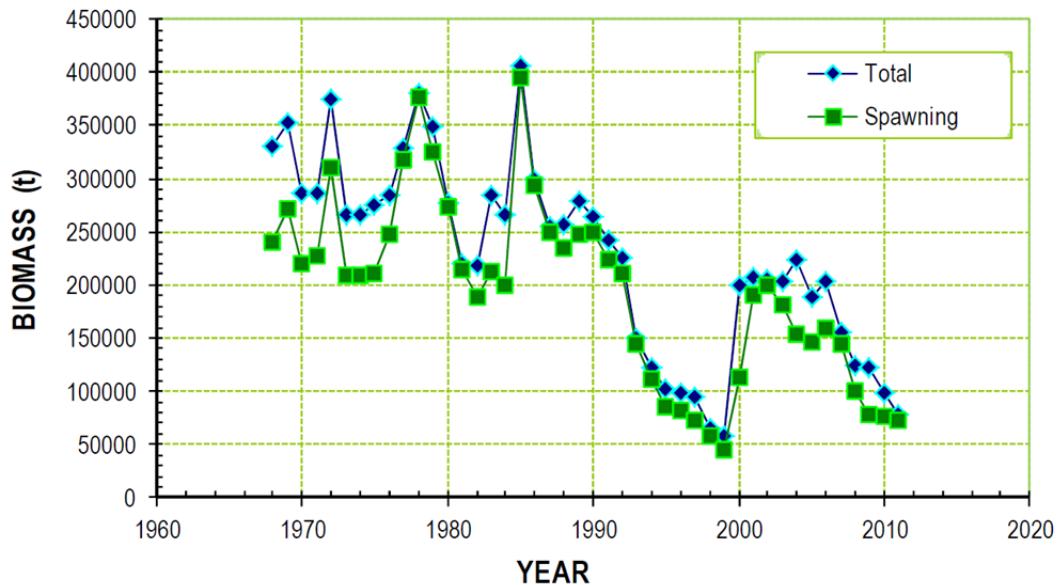

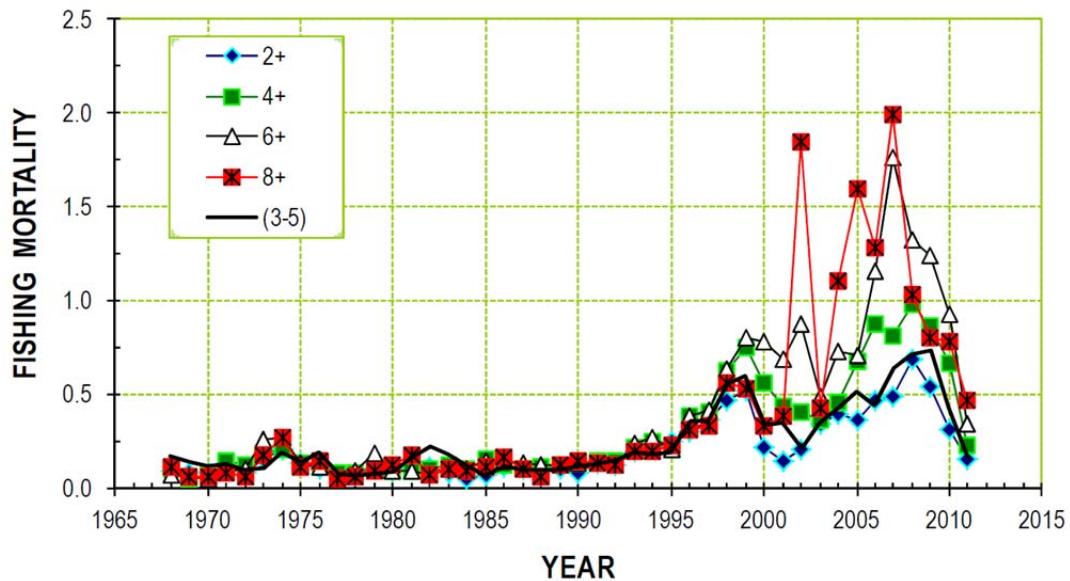

Figure 10: Atlantic mackerel fishing mortality in NAFO Subareas 3 and 4 from 1968 to 2011, estimated from a sequential population analysis of the Canadian contingent of mackerel (Reprinted from the 2012 Canadian assessment (DFO 2012, Figure 13)).

**Appendix:**  
**Spatial distribution of Atlantic mackerel landings**

Figure A1: Atlantic mackerel commercial landings from 2005-2009. Landings for all gears other than paired midwater trawl were reported via dealer reports matched to a vessel trip report (VTR). Landings for paired midwater trawl vessels were reported via VTRs. Total Dealer Landings reported (mt): 196,881.3. Dealer Landings from trips with location data (mt): 145,997.7 (74.2% of total).

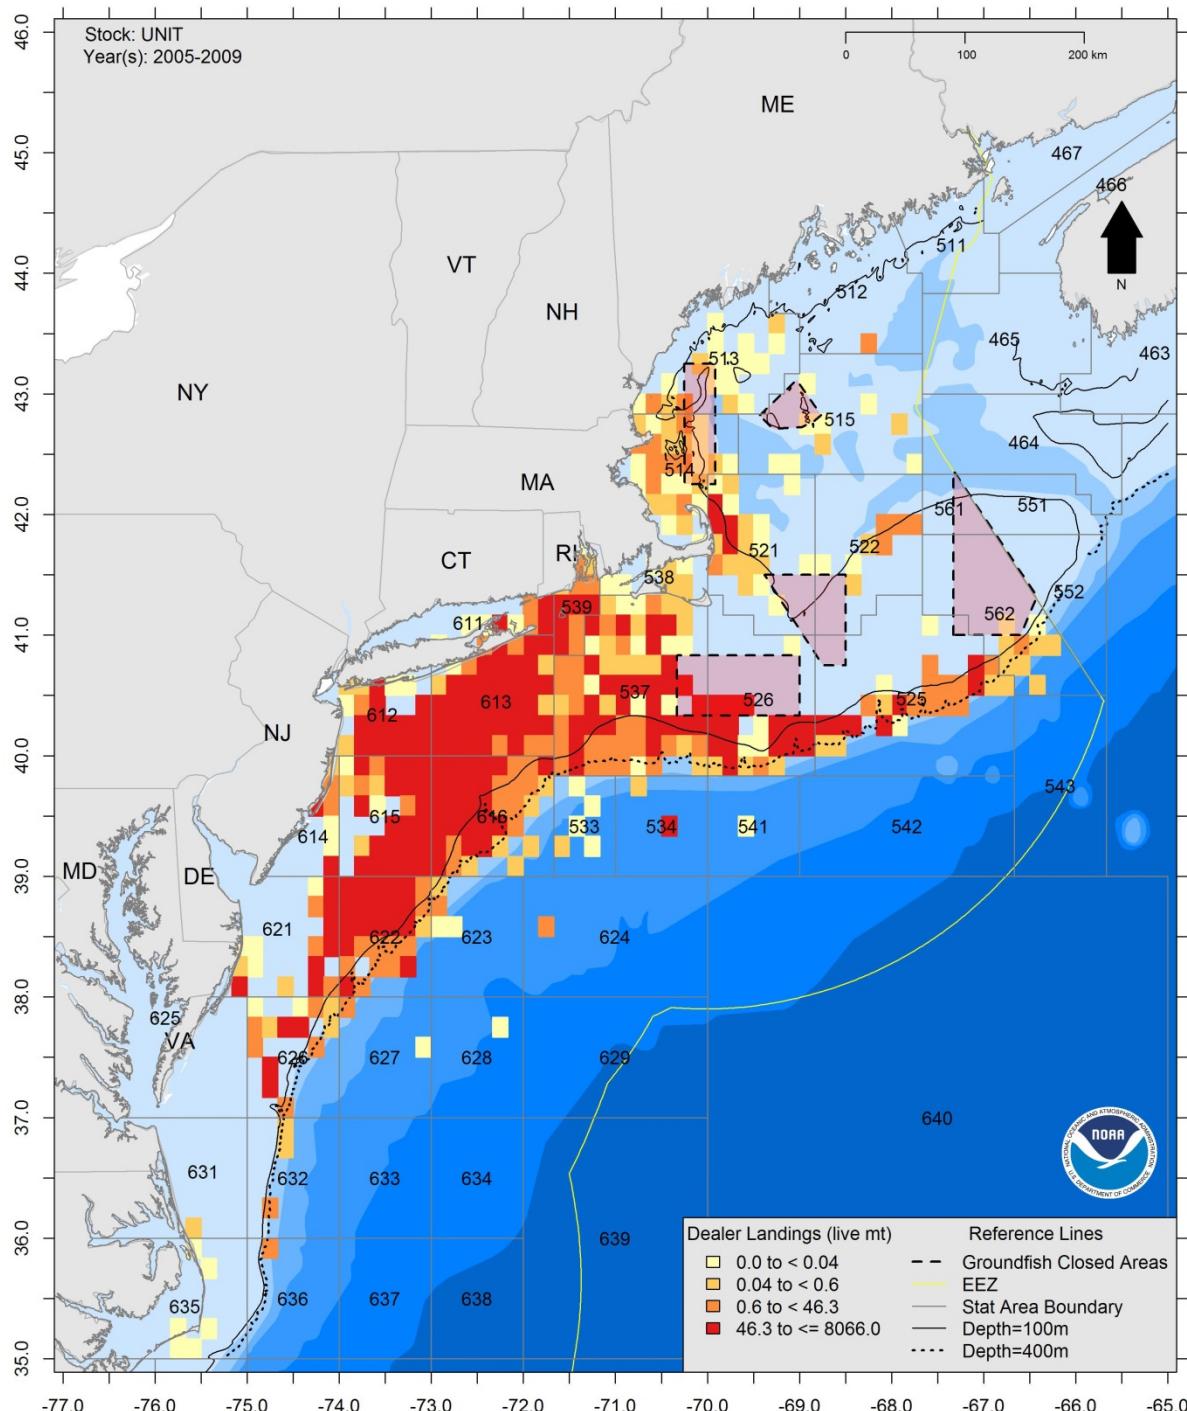

Figure A2: Atlantic mackerel commercial landings from 2010-2014. Landings for all gears other than paired midwater trawl were reported via dealer reports matched to a vessel trip report (VTR). Landings for paired midwater trawl vessels were reported via VTRs. Total Dealer Landings reported (mt): 25,713.0. Dealer Landings from trips with location data (mt): 23,388.9 (91.0% of total).

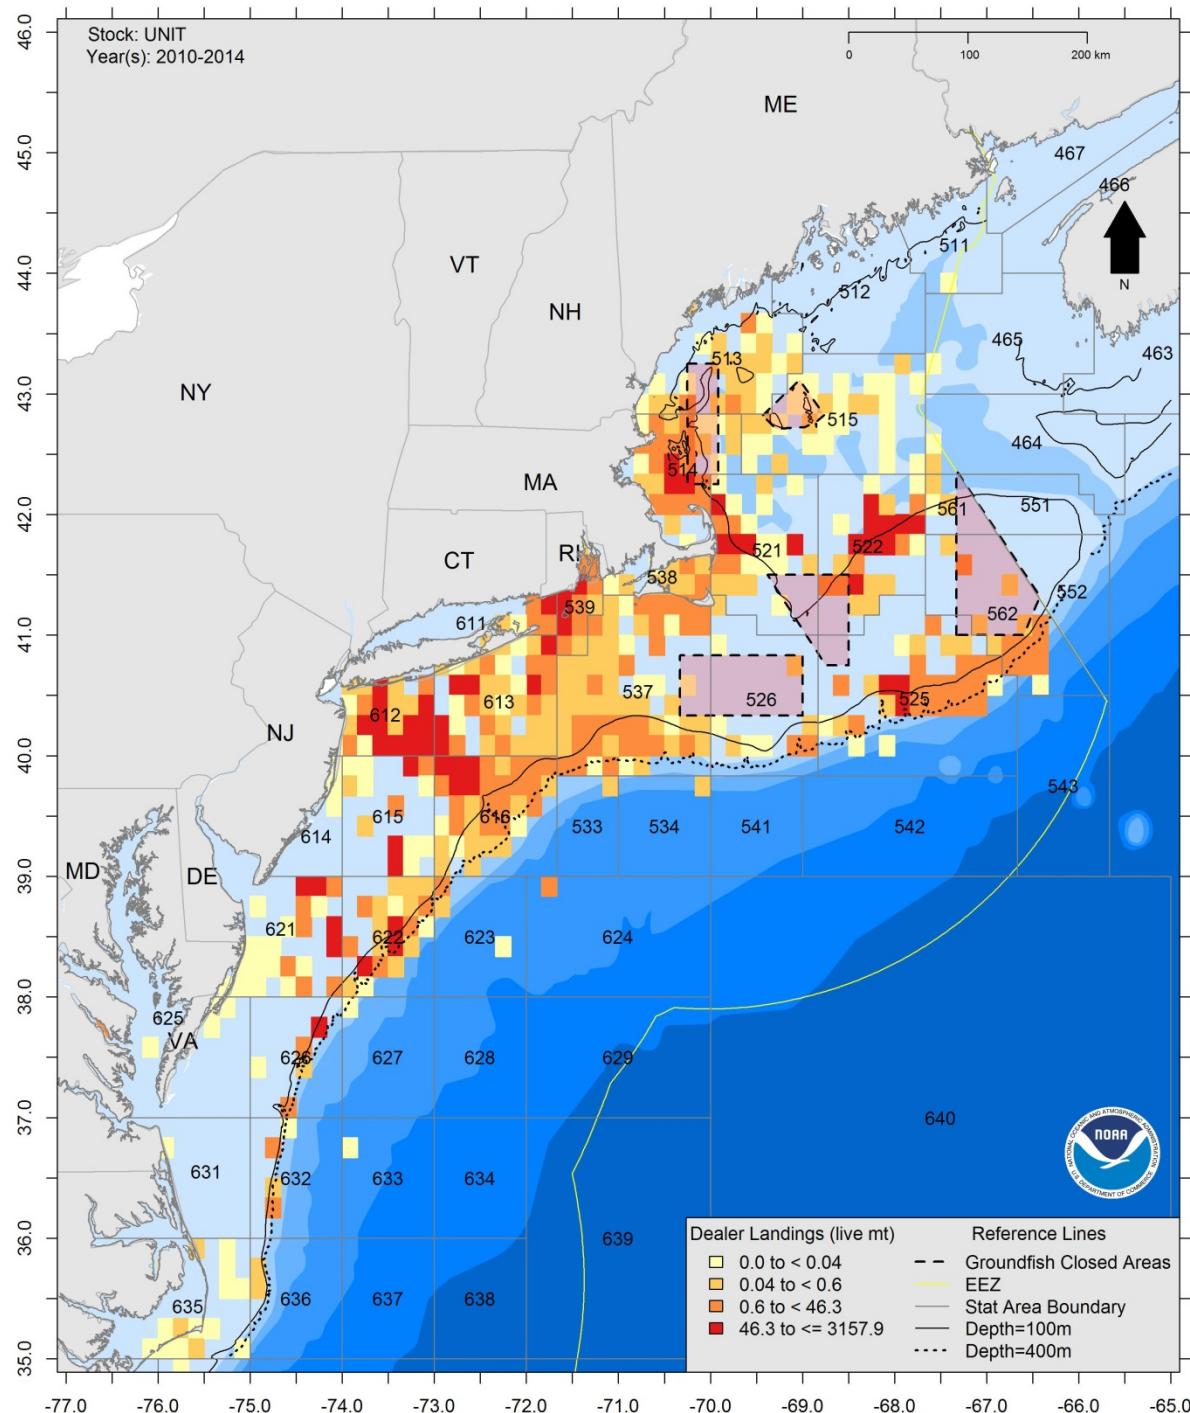

Figure A3: Atlantic mackerel commercial landings from 2015. Landings were reported via vessel trip reports (VTRs). Total VTR Landings reported (mt): 5,783.9. VTR Landings from trips with location data (mt): 5,684.9 (98.3% of total).
